© The Author(s) 2023

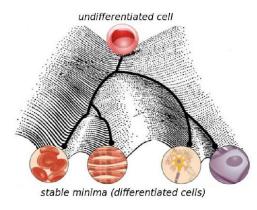

Directed acyclic graph depicting the relationships between stress and stress-related psychopathology and GrimAA. Green lines indicate causal or mediating paths. Pink lines indicate confounding paths. Minimally sufficient adjustment set (MSAS) for direct effect of stress and stress-related psychopathology on GrimAA = Tobacco Use + Alcohol Use + BMI + Physical Activity + Medical Illness + Blood Cell Composition + Sex + Race + Adult SES. MSAS for Total Effect = Adult SES + Race + Sex. Generated with daggity.net, modified for clarity. Supplementary Materials include code to reconstruct this DAG at dagitty.net. Protein synthesis (how much is espressed)

# EXPOSOME

# **Epigenetics vs Genetics**

How strong or long-lasting does the stimulus need to induce an epigenetic change?

The presence of a stressful event per se, i.e., the objective stress, and subjective stress, i.e., how stressful this event is perceived?

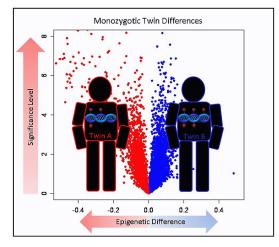

Genetically identical...

**Research Paper** 

Work-related stress and well-being in association with epigenetic age acceleration: A Northern Finland Birth Cohort 1966 Study

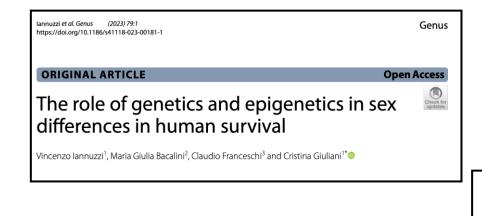

Anna Freni-Sterrantino<sup>1</sup>, Giovanni Fiorito<sup>1,2</sup>, Angelo D'Errico<sup>3</sup>, Oliver Robinson<sup>1</sup>, Marianna Virtanen<sup>4,5</sup>, Leena Ala-Mursula<sup>6</sup>, Marjo-Riitta Järvelin<sup>1,6</sup>, Justiina Ronkainen<sup>6</sup>, Paolo Vineis <sup>1,7,8</sup> Long working hours (>55hours/week) and shift work have been associated with increased risk of chronic conditions like stroke or breast cancer and working long hours is a risk factor for shortened sleeping hours and difficulty falling asleep

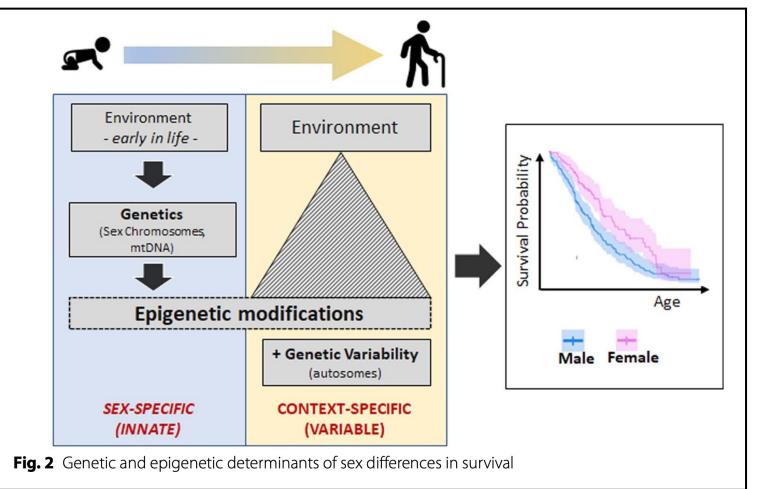

- Significant associations between work stress indicators and epigenetic age acceleration, limited to a range of ±2 years
- Association was found for working for more than 40 hours per week that increased the aging over 1.5 years, (HorvathAA β =2.058 95%CI 0.517,3.599, HannumAA β=1.567, 95%CI 0.415,2.719).

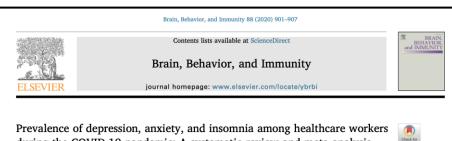

**Figure 1.** Increased susceptibility to some diseases and infections and to the effects of vaccinations and environmental factors in males (left panels) and females (right panels).

" Innate" mechanisms (both genetic and epigenetic) common to all males and to all females play a major role in sex differences in lifespan, but solely on their own are not sufficient to explain the magnitude of this gap between sexes

during the COVID-19 pandemic: A systematic review and meta-analysis Sofia Pappa<sup>a,b,+1</sup>, Vasiliki Ntella<sup>c,1</sup>, Timoleon Giannakas<sup>c</sup>, Vassilis G. Giannakoulis<sup>c</sup>, Eleni Papoutsi<sup>c</sup>. Paraskevi Katsaounou<sup>c,d</sup>

Median number of individuals per study was 1563 (range 134, 11118) with a median male representation of 18% (281.5/1563) and a median questionnaire participation rate of 85.3% (range 43.2%, 94.88%).

#### Highlights

•At least one in five healthcare professionals report symptoms of depression and anxiety.

•Almost four in ten healthcare workers experience sleeping difficulties and/or insomnia.

•<u>Rates of anxiety and depression were higher for FEMALES</u> healthcare workers and nursing staff.

•Milder mood symptoms are common and screening should aim to identify mild and sub-threshold syndromes.

#### Article **Investigating the Psychological Impact of COVID-19** among Healthcare Workers: A Meta-Analysis

Kavita Batra <sup>1,2,\*</sup>, Tejinder Pal Singh <sup>3</sup>, Manoj Sharma <sup>1</sup>, Ravi Batra <sup>4</sup> and Nena Schvaneveldt <sup>5</sup>

Sixty-five studies met the inclusion criteria and the total sample constituted 79,437 participants.

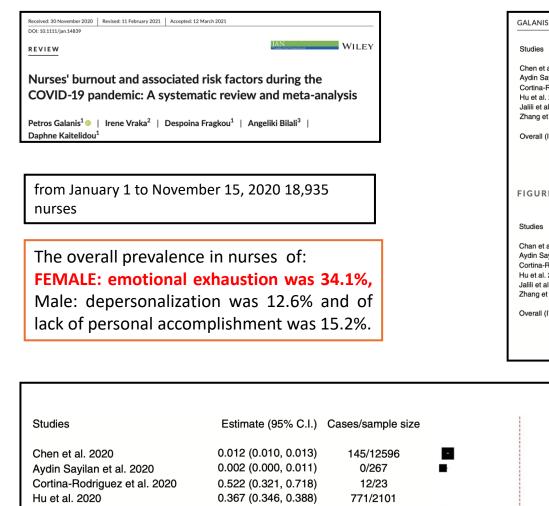

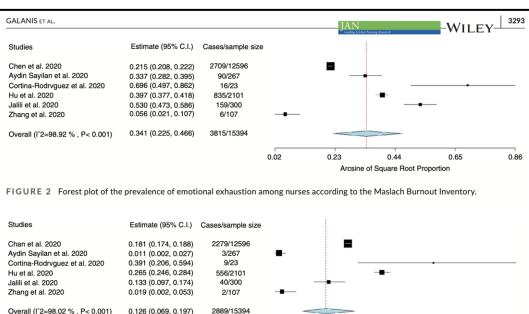

The pooled prevalence of anxiety, depression, stress, post-traumatic stress syndrome, insomnia, psychological distress, and burnout was 34.4%, 31.8%, 40.3%, 11.4%, 27.8%, 46.1%, and 37.4% respectively.

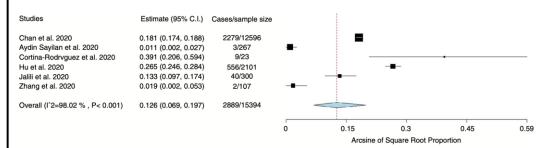

The subgroup analysis indicated **higher anxiety and depression prevalence among FEMALES**, nurses, and frontline responders than males, doctors, and second-line healthcare workers.

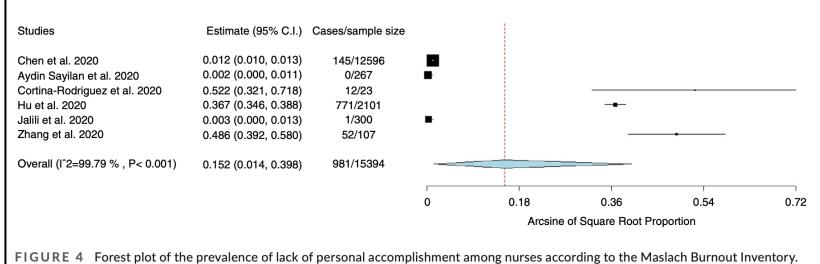

This study highlights the need for designing a targeted intervention to improve resilience and foster post-traumatic growth among frontline responders.

 Accute stress disorder, coping self-efficacy and subsequent

 psychological distress among nurses amid COVID-19

 Ghada Shahrour PhD, PMHCNS, RN, Assistant Professor<sup>1</sup> (10 M)

 Latefa Ali Dardas PhD, PMHN, Assistant Professor<sup>2</sup> (10 M)

A total of 448 Jordanian nurses (73% females).

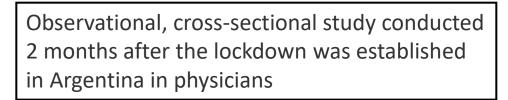

The majority of nurses (64%) are experiencing ASD due to the COVID-19 pandemic and thus are at risk for PTSD predisposition. **More than one-third of nurses (41%) are also suffering significant psychological distress.** 

Among our sample, age, ASD and coping self-efficacy significantly predicted psychological distress.

More specifically, **younger nurses** are more prone to experience psychological distress than older ones. While higher scores on ASD showed more resultant psychological distress, coping self-efficacy was a protective factor.

#### Prevalence of stress, burnout syndrome, anxiety, and depression among physicians of a teaching hospital during the COVID-19 pandemic

Prof. Francisco J. Appiani, M.D.<sup>a</sup>, Federico Rodríguez Cairoli, M.D.<sup>a</sup>, Prof. Luis Sarotto Jr., M.D.<sup>b</sup>, Claudio Yaryour, M.D.<sup>c</sup>, María E. Basile, M.D.<sup>a</sup> and Juan M. Duarte, M.D.<sup>a</sup>

- The prevalence of stress was 93.7 % (95 % confidence interval [CI]: 90.33-96.2), burnout syndrome 73.5 % (95 % CI: 68.2-78.4), anxiety 44 % (95 % CI: 38.4-49.8), and depression 21.9 % (95 % CI: 17.3-26.9).
- The frequency of burnout syndrome, anxiety, and depression was significantly higher among residents and physicians working in the emergency department
- The prevalence rate of anxiety and depression appeared to be higher in FEMALES,
- Less trained FEMALE workers had a higher prevalence of anxiety, depression, and post-traumatic stress disorder
- > No association was observed between the frequency and medical specialty.

Determinants of burnout and other aspects of psychological well-being in healthcare workers during the Covid-19 pandemic: A multinational cross-sectional study

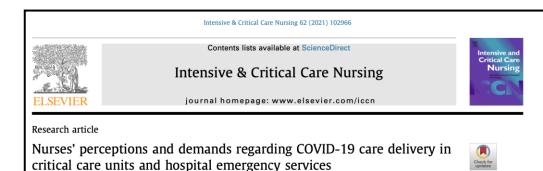

Max Denning<sup>1</sup>, Ee Teng Goh<sup>1</sup>, Benjamin Tan<sup>2</sup>, Abhiram Kanneganti<sup>3</sup>, Melanie Almonte<sup>1</sup>, Alasdair Scott<sup>3</sup>, Guy Martin<sup>1</sup>, Jonathan Clarke<sup>1</sup>, Viknesh Sounderajah<sup>1</sup>, Sheraz Markar<sup>1</sup>, Jan Przybylowicz<sup>1</sup>, Yiong Huak Chan<sup>4</sup>, Ching-Hui Sla<sup>2,5</sup>, Ying Xian Chua<sup>6</sup>, Kang Sim<sup>7,8</sup>, Lucas Lim<sup>9</sup>, Lifeng Tan<sup>10</sup>, Melanie Tan<sup>11</sup>, Vijay Sharma<sup>2</sup>, Shirley Ooi<sup>12,13</sup>, Jasmine Winter Beatty<sup>1</sup>, Kelsey Flott<sup>1</sup>, Sam Mason<sup>1</sup>, Swathikan Chidambaram<sup>1</sup>, Seema Yalamanchili<sup>1</sup>, Gabriela Zbikowska<sup>1</sup>, Jaroslaw Fedorowski<sup>14</sup>, Grazyna Dykowska<sup>15</sup>, Mary Wells<sup>1</sup>, Sanjay Purkayastha<sup>1+</sup>, James Kinross<sup>1</sup>

- clinical roles confer a higher burnout risk compared with non-clinical roles
- adapting to a new method of working,
- increased service demands,
- prolonged periods wearing personal protective equipment,
- feeling "powerless" to manage patients' conditions,
- fear of becoming infected or infecting others
- Staff who were redeployed to new clinical areas had a higher risk of burnout
- FEMALE gender was predictive of anxiety (OR 1.47), which is in keeping with previous findings during Covid-19
- However FEMALE gender was also found to be inversely correlated with depression, which contrasts from previous research

Stress recognition

**Fig 2. Radar plot demonstrating SAQ subscale by psychological state.** This figure demonstrates the SAQ subscale scores by psychological outcome. Distance from the centre represents proportion of a subscale answered positively. A greater distance represents a more positive score. § patients may be represented in more than one series. §§ Not all subscales are weighted equally in calculating overall SAQ score, the area of the radar plot will therefore not represent the overall SAQ score.

This is a cross-sectional study (the first phase of a mixed methods study) with critical care and emergency nurses from **26 public hospitals in Madrid** using an online questionnaire.

# 87% female nurses

The response rate was 557, with:

María Teresa González-Gil\*, Cristina González-Blázquez, Ana Isabel Parro-Moreno,

María Teresa Alcolea-Cosín, María Teresa Argüello-López, Coro Canalejas-Pérez,

María del Pilar Palazuelos-Puerta, Carmen Sellán-Soto, Cristina Oter-Quintana

Azucena Pedraz-Marcos, Ana Palmar-Santos, Laura Otero-García, María Victoria Navarta-Sánchez,

Asunción García-González, Eva García-Perea, Mercedes Martínez-Marcos, María Luisa Martínez-Martín,

María Elena Carrillo-Camacho, María Lourdes Casillas-Santana, María Luisa Díaz-Martínez,

- > 37.5% reporting working with the fear of becoming infected and its consequences,
- 28.2% reported elevated workloads,
- high patient-nurse ratios and shifts that did not allow them to disconnect or rest, while taking on more responsibilities when managing patients with COVID-19 (23.9%).

They also reported:

- deficiencies in communication with middle management (21.2%),
- inability to provide psycho-social care to patients and families
- being emotionally exhausted (53.5%),
- difficulty in venting emotions (44.9%).

COVID-19 anxiety among front-line nurses: Predictive role of organisational support, personal resilience and social support

Leodoro J. Labrague RN, DM, PhD, Lecturer<sup>1</sup> Janet Alexis A. De los Santos RN, MAN, PhD, Assistant Professor<sup>2</sup> 325 registered nurses from the Philippines using four standardized scales.

Results: Of the 325 nurses in the study, 123 (37.8%) were found to have dysfunctional levels of anxiety.

WILEY

Using multiple linear regression analyses, social support ( $\beta = -0.142$ , p = .011), personal resilience ( $\beta = -0.151$ , p = .008) and organisational support ( $\beta = -0.127$ , p = .023) predicted COVID-19 anxiety. Nurse characteristics were not associated with COVID-19 anxiety.

**Conclusions: RESILIENT NURSES** and those **who perceived higher organisation and social support** were more likely to report lower anxiety related to COVID-19.

PSYCHOLOGICAL ASPECTS OF CARDIOVASCULAR DISEASES (A STEPTOE, SECTION EDITOR)

#### Work Stress as a Risk Factor for Cardiovascular Disease

Mika Kivimäki<sup>1</sup> · Ichiro Kawachi<sup>2</sup>

600,000 men and women from 27 cohort studies in Europe, the USA and Japan suggests that work stressors, such as job strain and long working hours, are associated with a moderately elevated risk of incident coronary heart disease and stroke.

The excess risk for exposed individuals is **10–40 % compared** with those free of such stressors.

# A total of **5651 CVD-free participants older than 50 years** from the Survey of Health, Ageing and Retirement in Europe were followed up for 13 years to detect incident CVD.

## Results

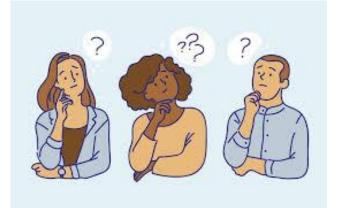

High physical demands (hazard ratio [HR], 1.30) and low reward (HR, 1.19) compared with their counterparts, as well as active physical jobs (HR, 1.41) and high physical strain (HR, 1.45) in comparison with low physical strain were associated with higher risk of incident CVD after adjusting for confounders.

### Conclusions

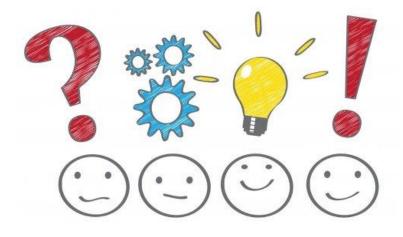

Avoiding physically stressful jobs or providing appropriate reward may reduce the occurrence of CVD.

# Conclusions

- Long working hours (>55hours/week) increased risk of chronic conditions like stroke or breast cancer and shortened sleeping hours and difficulty falling a sleep;
- ➢ Individual respose to stress; Female and male have a different response;
- Data from COVID-19 period highlighted significant stress related consequence in female and young health care professionals;
- Measures to provide maximum exposure period (i.e. four hours), facilitating breaks for basic needs and venting emotions can contribute to improving the physical and emotional wellbeing;
- Training and clinical practice guidelines with clear and precise instructions (for nurses);
- Interventions aimed at providing higher organization and social support can help the management of stress (i.e. mindfulness, aerobic exercise and bibliotherapy may also be successful)

Can gender difference and related stress response be partially related to a different approach to work and/or "a very meticulous and precise person" "hard on oneself aiming for perfection" from female?

Per contatti: Prof. Rosita Gabbianelli email: rosita.gabbianelli@unicam.it

Il corso di perfezionamento si prefigge l'obiettivo di introdurre farmacisti, biologi, medici, professionisti della nutrizione e docenti interessati alla nutrizione molecolare e funzionale, mediante lo sviluppo delle seguenti tematiche:

> MODULO 1: Introduzione alla nutrizione personalizzata

> > MODULO 2: Introduzione alla nutrigenomica

MODULO 3: Proprietà nutrigenomiche dei cibi

> MODULO 4: Nutrizione molecolare

MODULO 5: Nutrizione funzionale

Durata del percorso formativo: 250 ore di cui 55 di didattica frontale (mediante piattaforma webex di Ateneo)

Per informazioni sul corso di perfezionamento: nutrigenomics@unicam.it

#### Annual Review of Public Health

Understanding Health Inequalities Through the Lens of Social Epigenetics

Chantel L. Martin,<sup>1,2</sup> Lea Ghastine,<sup>1</sup> Evans K. Lodge,<sup>1,2,3</sup> Radhika Dhingra,<sup>4,5</sup> and Cavin K. Ward-Caviness<sup>6</sup>

Although maternal stress was not associated with preterm birth in their study, they found that higher prenatal stress was associated with increased offspring methylation in the *MEST* DMR, and the associations differed for male and female offspring.
